X-ray

What is it? Uses a small amount of radiation to take pictures inside your body.
Used for? Diagnosing broken bones, pneumonia, dental problems.
Mammograms are a common type of X-ray used to help diagnose breast cancer.
What happens? You may be asked to lie still on an X-ray table or sit or stand by the table. You may wear a lead apron to protect certain parts of your body.

Fact: The amount of radiation you get from an X-ray is small. For example, a chest X-ray gives out a radiation dose similar to the amount of radiation you’re naturally exposed to from the environment over 10 days.

CT or CAT scan (computed tomography)

What is it? Uses special X-ray equipment to take pictures that show a “slice” of your body.
Used for? Diagnosing broken bones, cancer, blood clots, abdominal conditions, internal bleeding.
What happens? You lie still on a table and may have to hold your breath for a short time. The CT machine is aimed at the part of your body the health care provider needs to see. For some CT scans you may receive a “contrast dye,” which makes parts of your body show up better. The dye may be given through an intravenous (IV) tube or a syringe in your arm. Some dye is given in a drink.

MRI (magnetic resonance imaging)

What is it? Uses a large magnet and radio waves to look inside your body.
Does not expose you to radiation.
Used for? Diagnosing conditions of the heart, blood vessels, kidneys, liver, and other organs. During pregnancy, a health care provider uses an ultrasound to look at the baby.
What happens? You lie on a table. The person giving the test places gel and a device called a transducer on your skin. The transducer sends out sound waves that bounce off tissues inside your body.

Tip: The MRI makes a lot of noise. You may be offered earplugs.

Ultrasound

What is it? Uses sound waves to create an image.
Does not expose you to radiation.
Used for? Diagnosing conditions of the heart, blood vessels, kidneys, liver, and other organs. During pregnancy, a health care provider uses an ultrasound to look at the baby.
What happens? You lie on a table. The person giving the test places gel and a device called a transducer on your skin. The transducer sends out sound waves that bounce off tissues inside your body.

Tip: Ask a friend or relative to be your support person and advocate. They can help you ask questions, write down answers and reassure you.

Nuclear scans

What is it? Uses radioactive substances and a special camera to see inside your body. These scans can show how organs, such as your heart and lungs, are working.
Used for? Diagnosing blood clots, cancer, heart disease, injuries, infections, thyroid problems.
What happens? Before the test, you receive a small amount of radioactive material, which makes parts of your body show up better. The material can be given through an intravenous (IV) tube or a syringe in your arm. Some is given in a drink and sometimes you inhale it. You wait as the material is absorbed by your body. This may take an hour or more. Then you lie still on a table while the camera takes images.

SpeakUp™: X-rays, MRIs and other medical imaging tests

Medical imaging tests help diagnose health problems. Some tests use radiation. Radiation is useful, even life-saving, but too much can be harmful.

Ask your health care provider:
- Why do you need this test?
- Does this test use radiation?
- Is there another test that does not use radiation?
- What can you expect during the test?
- What should you do to prepare for the test?
- Does the health care provider's office keep track of your medical imaging tests? You should also keep copies for your files.
- Does the hospital or imaging center use the lowest amount of radiation needed to get information – especially for children?
- Is the hospital or imaging center accredited?

Tip: Ask a friend or relative to be your support person and advocate. They can help you ask questions, write down answers and reassure you.
